Nurul Hiron Department of Electrical Engineering Faculty of Engineering Siliwangi University Indonesia hiron@unsil.ac.id

Abstract-In Citarum River, West Java, Indonesia, there are three serial reservoirs successively spreading out from upstream to downstream, namely Saguling Reservoir with the volume of 875 million m3and electrical energy production of 700 MW, Cirata Reservoir with the volume of 2,156 million m3 and electrical energy production of 500 MW. Jatiluhur Reservoir, the most downstream, with the volume of 2,451 million m3 and electrical energy production of 150 MW. Jatiluhur Reservoir also supplies for irrigation of 260,000 ha areas and drinking water industry with the average inflow of 100m3/s. Those reservoirs have highly fluctuated with maximum water level 5 m per month. This condition occurs as the sharing-non-sharing system is applied. Although this fluctuation is still in a normal condition, it affects the stability of reservoir slope. This study discusses the validation of a linear method to reach an optimal value of reservoir production in terms of electrical energy. The primary reservoir inflow data used was from 1988-2000, while the demand data was taken from 1992-2000, Cascade reservoir technique data was based on the existing data in 2000. Stochastic analysis was used to determine the inflow of 2000-2005 generation, while demand analysis was carried out using regression analysis. Multi-reservoir optimization analysis is carried out with linear simulation programs to obtain energy or fulfillment of demand every month, while demand for irrigation in the Jatiluhur reservoir is needed as a top priority supported by Saguling, Cirata, and Jatiluhur reservoirs as the next priority. The result of optimizing cascade reservoir from 2001-2005, with an initial period of operation on April obtained an average electrical production of 4,996.5 GWh, shows that the realization of average electrical production is 4,141.96 GWh. Besides, the average demand is 4,996.8 MCm, while the average supply is 5.806.2 MCm.

Keywords—Optimization, Multi-reservoir Operation, Purpose Function, Prediction

I. INTRODUCTION,

Operating reservoir involves various capacities of storage that are divided into some parts based on the function having planned in reservoir operation. The type of reservoir operation implicates some regulations that influence decision making, including storage capacity and water outflow management with various purposes.

XXX-X-XXXX-XXXX-X/XX/\$XX.00 ©20XX IEEE

They are operating multi-reservoir with multi-purpose needs to pay attention to the importance and function of each reservoir. One objective function probably used is to maximize the electrical energy with the required water release from the downstream reservoir must be higher than or same as required constraints. Besides, the multi-reservoir operation should pay attention to the required constraints and constraints that fulfill many interests. In general, the <u>followings are</u> some constraints <u>that are</u> often used in operating the multi-reservoir system<u>;-are the followings</u>.

- 1. Final water level ≥ Initial water level
- 2. The final water level of each reservoir \leq Maximum operating water level
- The final water level of each reservoir ≥ Minimum operating water level
- 4. Water release from multi-purpose reservoir ≥ Irrigation needs

Related to operation optimization of reservoirs in a Journal entitled; "Optimal crop plans for a multireservoir system having intra-basin water transfer using multi-objective evolutionary algorithms coupled with Chao" [1] as follows a surface water reservoir serves multiple purposes such as irrigation, hydropower generation, industrial and domestic water supply, flood control, navigation, recreation, etc. Among these purposes, irrigation is most significant in India since irrigated agriculture is the largest consumer of water.

A. RULE CURVES AND WATER CONTROL DIAGRAMS

The terms *rule curve* and *guide curve* are typically used to denote operating rules which define ideal or target storage levels and provide a mechanism for release rules to be specified as a function of storage containers. Rule curves aretypically expressed as water surface elevation or storage volume versus time of the year. **Commented** [i-[1]: The english of the manuscript must be proofread

Commented [i-[2]: Since all authors are from two university, the afiliation only need in two column

Commented [i-[3]: The abstrcts need to be reduced.

Commented [i-[4]: You need to revised this sentences in to two or the sentences that indicate the general problem of a river as a source of electical energy.

Commented [i-[5]: To indicate the contribution, more current literature study are needed.

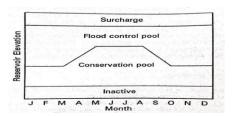

Figure 2-1 Seasonal top of conservation pool. [2]

B. Hydroelectric Power

Hydroelectric power is typically used for peak load, while thermal plants supply the baseload. Hydroelectric power plants can assume load rapidly and are very efficient for meeting peak-demand power needs. In some regions, hydroelectric power is a primary source of electricity, supplying much or most of the baseload as well as the peak load.

C. Linear Programming Format

Linear programming consists of finding values for a set of *n* decision variables $(x_1,x_2,...,x_n)$ that minimize or maximize an objective or criterion function x_0 of the form:

Where a_{ij} , b_i , and c_j are constants. The linear programming model is expressed is more concise notation as minimize (or maximize) $x_0 = \sum_{i=1}^{n} c_i x_i$

subject to
for
$$i = 1, 2, ..., m$$

$$(a-1)$$

$$\sum_{j=1}^{n} a_{ij} x_j \le b_i$$

$$(a-5)$$
and
$$x_j \ge 0$$
for $j =$

$$(a-6)$$

Where x_0 is the objective function, x_j are the decision variables. c_j , a_{ij} , and b_i are constants, n is the number of decision variables, and m is the number of constraints. The less than or equal sign in the constraint inequalities may be replaced by a greater than or equal sign to suit the particular problem being modeled. Maximizing $-x_0$ is equivalent to minimizing x_0 . The objective function and all constraints are a linear function or the decision variables. A set of values for the and variables is called a decision policy [3].

D. Stochastic Model

In statistics, the word of stochastic has <u>a</u> similar meaning with random. In hydrology, stochastic is particularly used in a time series in which some of them are random. In deterministic hydrology, a variable of time is important. Formulation of a model for monthly storage is developed by Thomas and Fearing, as follows [4].

$$\boldsymbol{q}_{i,j} = \boldsymbol{q}_j^- + \boldsymbol{b}_j \left(\boldsymbol{q}_{i-1,j-1} - \boldsymbol{q}_{j-1}^- \right) + \boldsymbol{t}_{i,j} \cdot \boldsymbol{S}_j \cdot \sqrt{\left(1 - \boldsymbol{r}_j^2\right)} \quad (1)$$

Where I is month in sequence, j = month in a year, j = 12, 1, 2 from January to December, $q_{i,j}$ is stored in the first month, j month in that year, $q_{i-1,j-1}$ is storage of previous month j, q_j^- is storage in month 'j' (average of month j (12 months are measured), b_j is regression coefficient from storage of months j and j-1 is r_j . s_j / s_{j-1} , (12 months are

measured), and r_j is correlation coefficient between storage of months j and j-1 (12 months are measured), S_j is deviation standard of month j(12 months are measured), $t_{i,j}$ is random variate, with an average of 0 and variant of 1.

In 1998, reservoir operation system was used for multireservoir operation pattern planning with an objective function to maximize the energy. There is a difference between the plan and its realization [5]. The prediction of monthly reservoir inflow is inappropriate with its realization. In consequence, there is a need to evaluate the pattern used to maintain the operation, including the initial water level and final water level, inflow and outflow, and electricity production [6].

Mathematic Model and Water Flow Pattern in Multipurpose Reservoir._-The formula is [7]:

$$V_{ij} = V_{Sij-1} + I_{ij} - Q_{ij} - Q_{ij} - O - E_{vpij-1} - I_{spilij}$$
 (2)

Where is the time index, j is the time index, S is reservoir index, I is inflow, O is water flow for irrigation, Q is outflow for powering turbine, E_{vpij} is water loss due to evaporation, I_{spilij} is water release through spillway [8].

II. METHOD AND MATERIAL

In Citarum River, it successively spreads out three reservoirs from upstream to downstream, namely Saguling with a maximum capacity of 889 x 10⁶ m³, Cirata (1,976 x 10⁶ m³), and Jatiluhur (2,458 x 10⁶ m³). The main function of Saguling and Cirata reservoirs is as hydroelectric power with each capacity of 700 MW (4x175 MW), 1000 MW (6x175 MW). Besides, Jatiluhur reservoir (6x30 MW) also provides irrigation water need for farmland of 260,000 ha, raw water for PAM Jaya and Industries.

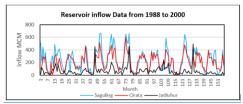

Fig. 1. The historical data inflow of the Saguling, Cirata, and Jatiluhur reservoir measured from 1988-2000

Fig.01 is a historical data inflow of the Saguling, Cirata, and Jatiluhur reservoir measured from 1988-2000. This historical data is then analyzed using the stochastic model from Thomas and Fearing, as in equation (1). The analysis result is a projection of Saguling, Cirata, and Jatiluhur reservoir inflow data for 2001-2005. Then the projection results are then compared with 2001-2005 field measurement data that has been provided from the Research and Development of Water Resources (Puslitbang Air) Bandung.

The comparison results are then validated by Thomas and Fearing's Stochastic Model accuracy. If the results of the comparison of projections resemble the field measurements, it can be said that the Thomas and Fearing model is valid for the inflow character in the Saguling, Cirata, and Jatiluhur reservoirs. Commented [i-[6]: All variable must be written in ittalic

| - | Formatted: English (United States) |
|---|---|

| | 1 cm |

In Jatiluhur Reservoir, there are six units of the turbine with the installed power of 187 MW and average electrical energy of 1,000 million KWH/month. Additionally, Jatiluhur Reservoir provides irrigation water for rice fields of 260,000 ha (twice planting period in a year), raw water, drinking water, fishery cultivation, flood control. Due to its vital function, water flowed from the Jatiluhur Reservoir must be higher than or the same as irrigation water needs.

This study aims to do-conduct an optimization with an operational simulation of multi-reservoir regarding monthly inflow in five years in Saguling, Cirata, and Jatiluhur Reservoirs. This optimization intends to maximize the energy of each reservoir.

III. RESULT AND DISCUSSION

Generating data from the three reservoirs have similarities with data resulted by observation from 2001 --2005 while the results of optimization with simulation as boundary condition with priority scale, energy and Irrigation demand can be met as shown in the table and graph, which one :

Inflow data of each hydroelectric power is used as an input for optimization with simulation. This section is a trial period of the initial operation.

The initial period of operation for Cascade Reservoir is in April. Water irrigation needs or demand based on the result of prediction with linear regression between 2001 and 2005 indicates that Demand Projection increases with the average number of 4.47%.

The result of optimization with simulation obtains the average number of monthly power, high flow of each link, release, downstream release, monthly storage of reservoir, spill, and supply for the demand.

If the storage of each reservoir in a certain month is lower than the minimum water level, it seems that the reservoir will be unstable. Consequently, to make the operation of each reservoir in a year in a balanced state, the storage of eachreservoir at the end of operation has to become in a similar condition by decreasing target of energy. The decreasing the target of energy deals with the decreasing capacity of a link or changing the beginning period of operation. **Commented** [i-[9]: All font size of the variable must reduces based on the format

| Formatted: figure caption, Left |

The optimization with simulation between 2001 to 2005, in which April become the beginning period of operation, reveals an optimal result and become target output of energy that is appropriate with demand constraint given. This implies that from April 2001 to April 2005, those reservoirs can be maintained well. April is still in the rainy season, so the storage of the reservoir is in full condition.

The result of reservoir operation due to the change of demand between 2001 and 2005 shows target output of energy that is appropriate with demand constraint given.

The management of multi-reservoir system for flood control is applied considering a high rainfall. For example, in Java island from January to April or even to June, July or August, rainfall is in high intensity. Hence, a huge flood will happen around those months.

One function of Saguling, Cirata, and Jatiluhur reservoirs are to control flood. For example, if flood level being controlled is twice minimum water level of the reservoir, storage of each reservoir at the moment of the flood is the <u>below: 1.</u> Saguling: $V \le V \max - 2 V \min$

$$= 889 - 2(272) = 345 \text{ MCM.}$$
2. Cirata =: V ≤ V max
= 1976 - (-1976 - 1177) 1576,5 MCM.
3. Jatiluhur =: V ≤ V max - 2 V min
= 2458 - 2 (599) = 1260 MCM

$$= 2458 - 2(599) = 1260 \text{ MCM}_{*}$$

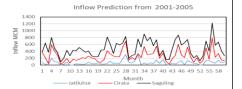

Figure Fig 55.1. Inflow pPrediction Saguling, Cirata, and Jatiluhur

Fig 5. Shows the prediction results of Cubic Milion Inflow Meter (MCM) in 2001-2005, for each Saguling, Cirata, and Jatiluhur inflow reservoir, using the stochastic method from Thomas fiering model as in equation (1). Calculations using the normal distribution. From the prediction results, the average inflow values obtained in the predicted year are 222 MCM for Saguling Reservoir, 190 MCM for Cirata, and 73 MCM for Jatiluhur Reservoir.

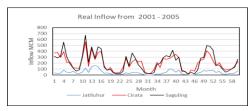

Figure Fig. 65.2. Real Inflow 2001 - 2005

Fig.6 is the measured real data, obtained from the head office of the research and development of water resources (Puslitbang Air) Bandung. From the results of monthly measurements on the three reservoirs, the average inflow values obtained in the predicted year are 290 MCM for Saguling Reservoir, 190 MCM for Cirata, and 52 MCM for Jatiluhur Reservoir.

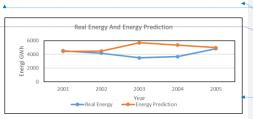

Chart Fig. 75.3. Real Energy And Energy Prediction in GWh

Fig. 7 is a comparison chart of energy produced from the three reservoirs, which for Real energy data is obtained from Perum Jasa Tirta II (PJT.II) with an average energy each year from the three reservoirs of 4142 GWh while prediction of the average energy obtained from the results of optimization with simulations in 4997.4 GWh.

Chart Fig. 85.4. Demand In Year in Jatiluhur Reservoir, MCM

In Fig. 8, it is a comparison between demand for irrigation (MCM) against prediction results using equation (1) and the measurement data from the three reservoirs. It is known that the irrigation demand for agricultural purposes, for around the reservoir area in 2001 - 2005, can be fulfilled by the availability of water in the Jailuhur reservoir. As in Fig 3, know that the Jatiluhur reservoir is a final reservoir which functions to meet agricultural irrigation needs.

From Fig 8, it is known that the growth of irrigation needs, which is 5 MCM/year is 4.8 (MCM), while the predicted results of the capacity of the Jatiluhur reservoir are not much different from the field measurement results, which is 5.81 MCM, thus it can be concluded that Jatiluhur is able to serve the needs irrigation.

From the results of this analysis, it is known that equation-(1) of Thomas and Fearing can be used as an alternative in analyzing the predicted growth of reservoir capacity on energy needs and agricultural irrigation needs.

IV. CONCLUSION

The result of this paper has obtained some facts that can be highlights high lightfor the current condition in the field Formatted: Body Text, Left, Line spacing: single

and future research. The average increase number of monthly demand for next year as much as 4.47%. By the-increasing the number of demand, the need is still fulfilled. The average energy of those reservoirs between 2001 and 2005 is 4.952 GWH, while real energy is 4,638 GWH. The initial period of operation that fulfills optimal requirement is in April because it can fulfill the objective function and its obstacles. There is the the an-increasing number of demand for irrigation need, industry and drinking water and it should become a priority, the movement of reforestation or the maintenance of Drainage Basin of Citarum River in upstream or downstream has to be carried out continuously, so the inflow of each reservoir can be fulfilled.
